SWGDAM Validation Guidelines for DNA Analysis Methods: Overview Document

The Scientific Working Group on DNA Analysis Methods, better known by its acronym of SWGDAM, is a group of approximately 50 scientists representing Federal, State, and Local forensic DNA laboratories in the United States and Canada. During meetings, which are held twice a year, Committees discuss topics of interest to the forensic DNA community and often develop documents to provide direction and guidance for the community.

26 This document was presented to the full SWGDAM group and received approval by the
27 membership on **date**. The SWGDAM Executive Board approved posting of the
28 document, with minor revisions, on **date**.

29

SWGDM Validation Guidelines for DNA Analysis Methods: Overview Document

Approved (date)

30 In the forensic context, the term “validation” refers to the process by which a procedure is
31 evaluated to determine its efficacy and reliability for forensic application. This document
32 and subsequent modules provide guidelines for the validation of DNA analysis methods
33 and supersedes the Scientific Working Group on DNA Analysis Methods (SWGDM)
34 revised Validation Guidelines (2016). These recommendations are intended to serve as a
35 guide for laboratories in validating procedures consistent with the FBI Director’s Quality
36 Assurance Standards (QAS). Terms used in this document and subsequent modules are
37 intended to be consistent with definitions provided in the QAS.

38

39 Because these are guidelines and not minimum standards, in the event of a conflict
40 between the QAS and these guidelines, the QAS and the QAS Audit Documents have
41 precedence over these guidelines. Additionally, to avoid any such conflict, use of the
42 mandatory term ‘shall’ has been used when that term is similarly used in the QAS
43 although the use of the term ‘shall’ is not intended to transform these guidelines into
44 standards.

45

46 These guidelines are not intended to be applied retroactively. Laboratories are
47 encouraged to review their standard operating procedures and validation protocols in
48 light of these guidelines and to update their procedures as needed.

49

50 **1. Introduction**

51 The SWGDM Validation Guidelines (2016) were updated to assist laboratories in
52 establishing reliable methods for DNA analysis and identifying limitations of the
53 procedures. Each laboratory seeking to evaluate a new system must determine which
54 validation studies are relevant to the methodology, in the context of its application, and
55 determine the experiments required to satisfy each study. These guidelines are applicable
56 to most methods used in DNA analysis. Some studies described herein may also assist in
57 conducting performance checks of procedural modifications to existing standard
58 operating procedures.

SWGDM Validation Guidelines for DNA Analysis Methods: Overview Document

Approved (date)

59 Performing internal validation studies can be a time consuming and laborious process.
60 Laboratories are encouraged to communicate and discuss plans and experiences regarding
61 validation workflows, including similar methods, which may save time and resources.

62

63 Laboratories validating a new platform, kit, reagents and/or procedure are encouraged to
64 publish validation studies in a peer-reviewed journal. Publication provides access to
65 information other laboratories can use to guide their internal validation efforts.

66 Utilization of published validation data from laboratories increases efficiency through
67 shared experience, provides a valuable crosscheck of original validity and enables
68 ongoing improvements, and as a result, is strongly encouraged to promote consistency
69 and demonstrate concordance among laboratories.

70

71 These Validation Guidelines have been organized such that required elements of
72 validation studies and a glossary are contained herein (referred to as the “Overview”
73 document). The Overview document will be supplemented by modules intended to
74 provide technology or methodology specific guidance. The studies in each module are
75 not synchronized to the FBI QAS; instead, they are presented in a suggested order to
76 conserve resources such as time, reagents, samples and consumables and streamline
77 required testing. These modules will be continually added or edited as necessary and will
78 be reflected in the SWGDAM Validation Guidelines for DNA Analysis Methods:
79 Modules List which can be found here: SWGDM.org/publications.

80

81 **2. General Considerations**

82 The purpose of validation is to demonstrate the reliability and potential limitations of a
83 technology or methodology. There are two types of validation required to implement or
84 modify technologies for forensic DNA analysis – developmental and internal. The
85 application of existing technology to the analysis of forensic samples does not necessarily
86 create a new technology or methodology. Published developmental validation studies in
87 other fields may sufficiently address forensic applications.

SWGDM Validation Guidelines for DNA Analysis Methods: Overview Document

Approved (date)

- 88 2.1 Developmental validation shall precede the implementation of any new methods
89 used for forensic DNA analysis.
- 90 2.1.1 Peer-reviewed publication of the underlying scientific principle(s) of a
91 technology shall be required.
- 92 2.1.2 Peer-reviewed publication of developmental validation studies is strongly
93 encouraged. However, validated technologies or procedures may be
94 implemented without such publication.
- 95 2.1.3 A DNA laboratory may rely upon another laboratory's published
96 developmental validation studies. The citations and/or publications
97 referencing that validation should be available and accessible to support
98 the underlying scientific basis.
- 99
- 100 2.2 Prior to using a method or procedure for forensic applications, a laboratory
101 shall conduct internal validation studies on samples representative of those
102 typically encountered by the end-user laboratory to demonstrate the reliability and
103 potential limitations of the method.
- 104 2.2.1 Internal validation studies including the approval of the technical leader,
105 shall be retained and available for review. Documentation, at a minimum,
106 should include:
- 107 2.2.1.1 Summary of each study conducted
- 108 2.2.1.2 Results of each study, including generated data
- 109 2.2.1.3 Approval of the technical leader for implementation
- 110 2.2.2 Standard operating procedures, quality assurance parameters, and
111 interpretation guidelines shall be derived from internal validation studies.
112 For example, lower template DNA may cause extreme heterozygote
113 imbalance; as such, empirical heterozygote peak-height ratio data could be
114 used to formulate mixture interpretation guidelines and determine the
115 appropriate ratio by which two peaks are determined to be heterozygotes.
116 In addition to establishing an analytical threshold, results from sensitivity
117 studies could be used to determine the extent and parameters of quality

SWGDM Validation Guidelines for DNA Analysis Methods: Overview Document

Approved (date)

118 control tests that reagents or instruments require prior to their being used
119 in actual casework.

120 2.2.3 For laboratory systems that consist of more than one laboratory, each of
121 the laboratories shall complete, document, and maintain studies which
122 may be impacted by site-specific factors (such as precision, sensitivity,
123 contamination, etc.). Studies that are not location-specific may be shared
124 among locations and the summary of the shared validation data shall be
125 available at each site.

126 2.2.4 Control samples (e.g., HL60, 2800M, 9947A, SRM, 007, and others) are
127 *NOT* to be considered known samples. These positive controls are not
128 subjected to the same laboratory processes and are therefore known to
129 behave differently. Control samples can be included but are not to be
130 considered the ‘known’ samples for these experiments.

131 2.2.4.1 It is important to utilize samples as part of the internal validation
132 studies that are extracted DNA obtained from the laboratory’s
133 validated procedures.

134

135 3. Developmental Validation

136 The developmental validation process shall include, where applicable, the following
137 studies using samples that are representative of those typically encountered by the end
138 user laboratory:

139 3.1 **Characterization of genetic markers:** The basic characteristics (described
140 below) of a genetic marker shall be determined and documented.

141 3.1.1 Inheritance: The mode of inheritance of DNA markers demonstrated
142 through family studies.

143 3.1.2 Mapping: The genomic location of the genetic marker.

144 3.1.3 Detection: Technological basis for identifying the genetic marker (e.g.,
145 capillary electrophoresis, DNA sequencing, hybridization assays).

146 3.1.4 Polymorphism: Type of variation (e.g., sequence and/or length variants).

147 **3.2 Species specificity:** The ability to detect genetic information from non-targeted
148 species (e.g., detection of microbial DNA in a human assay) shall be determined
149 through laboratory studies and/or sequence homology searches against genomic
150 databases (e.g., a BLAST search). The detection of genetic information from
151 non-targeted species does not necessarily invalidate the use of the assay, but may
152 help define the limits of the assay. Species cross-reactivity may be demonstrated
153 by using a number of commercially available non-human DNA at quantities
154 similar to that of the targeted application.

155

156 **3.3 Sensitivity studies:** The ability to obtain reliable results from a range of DNA
157 quantities, to include the upper and lower limits of the assay, shall be evaluated.

158

159 **3.4 Stability studies:** The ability to obtain results from DNA recovered from
160 biological samples deposited on various substrates and subjected to various
161 environmental and chemical insults should be evaluated. In most instances,
162 assessment of the effects of these factors on new forensic DNA procedures is not
163 required. However, if substrates and/or environmental and/or chemical insults
164 could potentially affect the analytical process, then the process shall be evaluated
165 to determine the effects of such factors.

166 **3.4.1** For database samples, stability studies may include samples on various
167 substrates and subjected to potential PCR inhibitors or various storage
168 conditions.

169

170 **3.5 Precision and accuracy studies:** The ability of the assay to obtain repeatable
171 and/or reproducible results must be determined, when practicable. The measure
172 of precision is usually expressed in terms of imprecision and computed as a
173 standard deviation of the test results while the measure of accuracy can be
174 accomplished by checking results against an appropriate and available certified
175 reference material.

176 **3.6 Case-type samples:** The ability to obtain reliable results should be evaluated
177 using samples that are representative of those typically encountered by the end-
178 user laboratory. Where appropriate, consistency of typing results should be
179 demonstrated by comparing results from the previous procedures to those
180 obtained using the new procedure.

181

182 **3.7 Population studies:** The distribution of genetic markers in populations (i.e.,
183 frequencies) should be determined in relevant population groups. When
184 appropriate, (e.g., novel markers and/or alleles), databases should be tested for
185 independence expectations (e.g., Hardy Weinberg Equilibrium and Linkage
186 Equilibrium).

187

188 **3.8 Mixture studies:** The ability to obtain reliable results from mixed-source samples
189 shall be determined. These studies will assist the laboratory in establishing
190 guidelines for mixture interpretation, which may include determination of the
191 number of contributors to the mixture, determination of the major and minor
192 contributor profiles, and contributor ratios or proportions in addition to
193 male:autosomal or male:female DNA quantification determination. These are
194 best achieved by varying the number of contributors, mixture ratios, and overall
195 template amounts.

196

197 **3.9 PCR-based studies**

198 **3.9.1** Publication of the sequence of individual primers is not required in order to
199 appropriately demonstrate the reliability and limitations of PCR-based
200 technologies. However, availability of the primer sequences is encouraged
201 in order to aid in the identification of potential primer binding site variants
202 and troubleshooting. PCR-based studies should include:

203 **3.9.1.1** The reaction conditions needed to provide the required degree of
204 specificity and robustness shall be determined. These include, but are

SWGDM Validation Guidelines for DNA Analysis Methods: Overview Document

Approved (date)

205 not limited to, thermal cycling parameters, the concentration of
206 primers, buffers, magnesium chloride, dNTPs and DNA polymerase.

207 3.9.1.2 The potential for differential amplification among loci, preferential
208 amplification of alleles within a locus, and stochastic amplification
209 should be assessed to measure the specificity and robustness of the
210 PCR reaction and the impact on peak height balance between and
211 within a genetic marker.

212 3.9.1.3 The effects of multiplexing should be assessed to measure the
213 specificity and robustness of the PCR reaction.

214 3.9.1.4 Appropriate controls should be assessed to ensure that the method
215 works correctly and ensure the data are valid.

216 3.9.1.5 Criteria for detection of amplified product should be determined based
217 on the platform and/or method used and instrument baseline noise
218 should be defined for quantitative and capillary electrophoresis typing
219 methods.

220 3.9.1.6 Appropriate measurement standards (qualitative and/or quantitative)
221 for characterizing the alleles or resulting DNA product shall be
222 established.

223

224 **4. Internal Validation**

225

226 4.1 The internal validation process shall include the applicable studies detailed below
227 and outlined in the relevant module(s). If conducted within the same laboratory,
228 developmental validation studies may satisfy some elements of the internal
229 validation. A laboratory's internal validation can be used to supplement any
230 elements in which the developmental validation is insufficient.

231

232 4.2 The laboratory should evaluate the suitability of each study based on the
233 methodology and/or application. If the lab determines that a study is not
234 applicable, the reason(s) shall be documented in the validation summary. Using

SWGDM Validation Guidelines for DNA Analysis Methods: Overview Document

Approved (date)

235 the specific module(s) as guidance, the laboratory should determine the
236 appropriate number of samples and the type of samples required for each study to
237 demonstrate the potential limitations and reliability of the method. It is
238 recognized that a validation study cannot account for all potential casework
239 scenarios; however, samples representing the range of forensic sample types
240 expected to be routinely encountered by the end-user laboratory should be
241 selected for evaluation.

242

243 4.3 At the time of validating new DNA methods (from amplification through
244 characterization), typing test kit, or platform instrument model, the laboratory
245 shall check results from the new method/kit/platform for concordance with an
246 appropriate and available certified reference material (or sample made traceable to
247 the certified reference material) prior to the implementation of the method for
248 forensic analysis.

249

250 Internal validation data may be shared by all locations in a multi-laboratory
251 system. The summary of the shared validation data shall be available at each site.
252 At a minimum, each laboratory in a multi-laboratory system shall complete,
253 document, and maintain applicable site-specific precision, sensitivity, and
254 contamination assessment studies.

255

256 4.4 Internal validation studies shall be documented and summarized. Internal
257 validation studies shall be reviewed by the technical leader and approval
258 documented prior to implementing a procedure for forensic applications.

259

260 4.5 The internal validation process shall include the studies detailed below, as
261 applicable:

262 4.5.1 **Known and non-probative evidence samples or mock evidence**
263 **samples:**

SWGDM Validation Guidelines for DNA Analysis Methods: Overview Document

Approved (date)

264 4.5.1.1 Methods intended for casework samples shall be evaluated and tested
265 using known samples (e.g., reference blood or buccal samples) and
266 case type samples. Methods intended for database samples should be
267 evaluated and tested using known samples collected on the substrates
268 routinely encountered by the laboratory.

269 4.5.1.2 The known samples selected for the studies should exhibit a high level
270 of heterozygosity. The use of heterozygous samples will help
271 establish intra-locus balance metrics and aid in the determination of
272 appropriate interpretation thresholds.

273 4.5.1.3 Known and non-probative sample studies may be used to assess the
274 concordance of a method and therefore the degree of accuracy of the
275 system. The data generated can also help establish appropriate stutter
276 filters, supplement the noise and threshold calculations, and assess
277 potential contamination events associated with the method. Results
278 from these studies should be compared to the previous results of
279 known samples and/or non-probative evidence or mock case samples
280 to assess concordance. Observed discordance(s) should be
281 documented and, where possible, explained. The potential impact of
282 any discordance should be assessed.

283 4.5.1.4 Case type samples may include non-human DNA at template levels
284 similar to those expected to be routinely encountered during casework
285 analysis (e.g., mold, bacteria). Results of these studies can be used to
286 determine how non-human artifacts can be recognized and how their
287 presence will affect the interpretation of the DNA profile.

288 4.5.2 Sensitivity and Stochastic Studies:

289 4.5.2.1 The laboratory shall determine the sensitivity levels of the assay or
290 procedure. The known samples selected for the studies should exhibit
291 a high level of heterozygosity. The use of heterozygous samples will
292 help establish intra-locus balance metrics. Sensitivity studies are
293 performed to assess the ability to obtain reliable results from a range of

294 DNA quantities, to include the upper and lower limits of the assay, and
295 to determine the dynamic range, ideal target range, limit of detection,
296 heterozygote balance (e.g., peak height ratio), and the signal-to-noise
297 ratio associated with the assay. Sensitivity studies can also be used to
298 evaluate excessive random (stochastic) effects generally resulting from
299 low quantity and/or low quality samples.

300 **4.5.3 Precision and Accuracy Studies:**

301 4.5.3.1 Precision and accuracy of the assay/instrument shall demonstrate that
302 it is achieving the expected result and must also address repeatability
303 and/or reproducibility when practicable.

304 4.5.3.2 Precision depends only on the distribution of random errors and does
305 not relate to the true value or specified value. The measure of
306 precision is usually expressed in terms of imprecision and computed as
307 a standard deviation of the test results.

308 4.5.3.3 Accuracy of a measuring instrument is the ability of a measuring
309 instrument to give responses close to a true value. This can be
310 accomplished by checking results against an appropriate and available
311 certified reference material.

312 4.5.3.3.1 **Repeatability:** Precision and accuracy of results (e.g.,
313 quantitative and/or qualitative) of the same operator and/or
314 detection instrument should be evaluated.

315 4.5.3.3.2 **Reproducibility:** Precision and accuracy of results (e.g.,
316 quantitative and/or qualitative) among different operators
317 and/or detection instruments should be evaluated.

318 **4.5.4 Mixture Studies:**

319 4.5.4.1 Mixture studies consisting of samples that are representative of those
320 typically encountered by the end-user laboratory shall be performed.
321 For example, forensic DNA mixture studies should use known samples
322 that represent the number of contributors and the range of general
323 mixture types for which the procedure will be used in casework (e.g.,

SWGDM Validation Guidelines for DNA Analysis Methods: Overview Document

Approved (date)

324 mixture proportions and template quantities). These studies will help
325 establish interpretation guidelines to include: determination of the
326 number of contributors to the mixture, determination of the major and
327 minor contributor profiles, and contributor ratios/proportions. As an
328 additional example, laboratories validating a new extraction method
329 should include in the mixture studies the body fluids, and
330 combinations thereof, that are typically encountered by the end-user
331 laboratory.

332 4.5.5 Contamination Assessment:

333 4.5.5.1 Contamination studies shall be performed to evaluate and measure the
334 potential for the introduction of exogenous DNA at any point during
335 sample processing. Based on these studies, the laboratory should/can
336 determine ways to mitigate contamination and/or develop a policy for
337 data interpretation when contamination has been identified.

338 4.5.5.2 These studies also serve to assess the presence of potential
339 contaminants in the reagents used throughout the various sample
340 processes in the laboratory as well as assessing the efficacy of personal
341 protective equipment and cleaning protocols. The laboratory shall
342 evaluate, using negative controls and known samples, the detection of
343 exogenous DNA originating from reagents, consumables, other
344 samples, operator(s) and/or the laboratory environment.

345 4.5.5.3 Should contamination be encountered during the contamination
346 assessment studies, the origin of the event must be explored and
347 should be characterized, when possible. The validation should
348 establish procedures that will minimize the occurrence of a
349 contamination event. Technical procedures should detail how to
350 address contamination should it occur in casework analyses.

351

352

353

5. Procedure Modification

SWGDM Validation Guidelines for DNA Analysis Methods: Overview Document

Approved (date)

354 A procedure modification is an alteration of an existing analytical procedure that
355 may have a consequential effect(s) on analytical results and the change is outside the
356 initial scope of the original validation. Examples of a procedure modification include a
357 decrease in reaction volume of an amplification kit or a change in injection time for a
358 genetic analyzer.

359

360 5.1 A procedure modification must be evaluated prior to use with forensic samples.

361 The modified procedure must be evaluated by comparing the original procedure
362 to the modified procedure using similar samples to ensure concordance. The
363 laboratory should define the appropriate sample number, sample type, and the
364 studies necessary to evaluate the modification. The evaluation shall be
365 documented, reviewed by the technical leader and approval documented prior to
366 the implementation of the modified procedure into forensic applications.

367

368 5.2 If the procedure modification is determined to have an impact on the efficacy or
369 reliability of the forensic analysis (such as modifications that impact the efficacy
370 of the PCR process or the detection of DNA types), additional internal validation
371 studies (such as sensitivity and stochastic studies) may be necessary to
372 demonstrate the continued reliability and potential limitations of the method.

373

374 **6. Performance Check**

375 A performance check is a quality assurance measure to assess the functionality of
376 laboratory critical equipment and instruments that affect the accuracy and/or validity of
377 forensic sample analysis.

378

379 6.1 A laboratory shall have and follow a documented program for conducting
380 performance checks of critical instruments and equipment.

381 6.1.1 This program will document the laboratory protocol, the performance
382 characteristics and acceptance limits.

SWGDM Validation Guidelines for DNA Analysis Methods: Overview Document

Approved (date)

383 6.1.2 The laboratory should evaluate the appropriate sample number and type to
384 demonstrate the reliability of the instrument or equipment.

385 6.1.3 If the laboratory determines that a performance check study is not
386 necessary, the justification should be documented.

387 6.1.4 A laboratory's evaluation may also determine that additional performance
388 check studies are necessary.

389

390 6.2 If service is performed on a critical instrument or equipment, a performance check
391 is required before returning it to use for forensic analysis.

392

393 6.3 If the physical location or the environment of the instrument has been changed
394 (e.g., instrument moved to another room, significant remodeling of the room), a
395 performance check should be completed before returning it to use for casework
396 analysis.

397

398 6.4 After an internal validation has been performed on a critical instrument, each
399 additional critical instrument of the same make and model shall require a
400 performance check.

401 6.4.1 The performance check should demonstrate that results are reproducible
402 on the new critical instrument and that testing results associated with new
403 critical instrumentation is comparable to testing results generated during
404 the internal validation and acceptable for use within the laboratory.

405 6.4.2 If the laboratory determines that the new critical instrument is not within
406 acceptable parameters, then the laboratory must address the instrument
407 and/or procedure to minimize or mitigate the difference.

408

409

410

411

412

413 7. Software

414

415 7.1 Software or software tools used in a forensic laboratory that may have an impact
416 on the analytical procedure, interpretation or statistical calculations shall be
417 validated to ensure the software fulfills its intended purpose and is suitable for use
418 in the laboratory. This includes the following software uses:

- 419 • Software used as a component of instrumentation
- 420 • Software used for the analysis and/or interpretation of DNA data
- 421 • Software used for statistical calculations for forensic genetic
422 applications
- 423 • Software tools (e.g., macros, workbooks, LIMS) used for
424 analytical workflow

425 7.1.1 Software shall be evaluated to assess the suitability of the software for its
426 intended use in the laboratory and to determine the necessity of validation
427 studies and/or software testing. This evaluation shall include the
428 determination of which studies will and will not be conducted and shall be
429 documented.

430 Software validations including the summary and results shall be reviewed
431 by the laboratory's technical leader and approval documented prior to
432 implementation.

433 7.2 Modifications to software or a software upgrade that will have an impact on the
434 analytical process, interpretation or statistical calculations shall require validation.
435 For software upgrades or modifications, the laboratory should require a software
436 developer to provide written documentation, such as release notes, to explain the
437 purpose and scope of the modification.

438 7.2.1 The validation required for each software change is determined by the
439 type of change and the impact of the change on the operation of the
440 software.

SWGDM Validation Guidelines for DNA Analysis Methods: Overview Document

Approved (date)

441 7.2.1.1 A major revision to software or software tools that impact the
442 analytical process, interpretation or statistical calculations shall require
443 validation prior to implementation.

444 7.2.1.2 A minor revision to software or software tools that does not impact the
445 analytical process, interpretation or statistical calculations shall require
446 a (functional testing) performance check.

SWGDM Validation Guidelines for DNA Analysis Methods: Overview Document

Approved (date)

464

Document Version	Revision History
July 2003	Original. (Published in Forensic Science Communications in July 2004; available at http://www.fbi.gov/about-us/lab/forensic-science-communications/fsc/july2004/index.htm/standards/2004_03_standards02.htm)
November 2012	The document was revised to update the guidelines to incorporate changes to the FBI Director's Quality Assurance Standards (QAS). The revisions include: addition of a preface that describes the QAS have precedence over these guidelines; definitions added to Section 1 for critical instrument, methodology, precision and technology; revised description of developmental and internal validation in Section 2; added Table of recommended studies for internal validation in Section 4; and References and Suggested Reading added in a new Section 8.
November 2012	Approved by the SWGDAM membership.
December 2012	Approved by the SWGDAM Executive Board, with minor revisions, for posting on swgdam.org .
November 2016	The document was revised to address Next Generation Sequencing (NGS) technologies. Revisions include: new definitions in Section 1 for bioinformatics, index, library and next generation sequencing; revisions to the definitions in Section 1 for methodology and technology; the addition of NGS-specific studies to both Sections 3 and 4; and revisions to Section 7.
December 2016	Approved by the SWGDAM Executive Board, with minor revisions, for posting on www.swgdam.org .
July, 2021	This document was reformatted to a Validation Overview document with general information about validation testing. Specific technology or methodology validation information has been moved to a separate Module format for each topic.
