SWGDM Interpretation Guidelines for Y-Chromosome STR Typing by Forensic DNA Laboratories

The Scientific Working Group on DNA Analysis Methods, better known by its acronym of SWGDAM, is a group of scientists representing Federal, State, and Local forensic DNA laboratories in the United States and Canada.

During meetings, which are held twice a year, committees discuss topics of interest to the forensic DNA community and often develop documents to provide direction and guidance for the community.

The guidelines described herein supersede the *SWGDM Y-Chromosome STR Interpretation Guidelines* issued in 2014. This document contains several revisions to the 2014 guidelines and is intended to reflect the current state of

31 forensic Y-STR typing. SWGDAM intends for these guidelines to be applied prospectively.
32 Provided that work (validation, training, analysis, interpretation) performed prior to the issuance
33

SWGDM Interpretation Guidelines for Y-Chromosome STR Typing

34 of this revision was appropriate and scientifically valid, these revised guidelines are not intended
35 to invalidate or call into question the previous work or to be applied retroactively. This document
36 contains guidelines and not minimum standards. In the event of a conflict between the FBI
37 Quality Assurance Standards for Forensic DNA Testing or DNA Databasing Laboratories (QAS)
38 and these guidelines, the QAS and the QAS related audit guide and documents have precedence
39 over these guidelines. Absent any other directive, the use of the terms *shall* or *must* is not
40 intended to transform these guidelines into standards.

41 These guidelines are not intended to address the interpretation of analytical results from Y-STR
42 testing using enhanced low template DNA techniques. This document therefore does not offer
43 an opinion as to the validity of any enhanced detection methods (see Caddy et al. 2008 and
44 *SWGDM Guidelines for STR Enhanced Detection Methods* for more information).

45 Unlike previous versions, these guidelines are stated without further explanation included here.
46 Refer to the *Supplemental Information for the SWGDAM Interpretation Guidelines for Y-
47 Chromosome STR Typing by Forensic DNA Laboratories* document for further explanation of these
48 guidelines and extensive background information.

49 **Introduction**

50 The interpretation of DNA typing results, including the results of Y-STR testing, requires
51 professional judgment and expertise. Additionally, laboratories that analyze DNA samples for
52 forensic casework purposes are required by the Quality Assurance Standards for Forensic DNA
53 Testing Laboratories to establish and follow documented procedures for the interpretation and
54 reporting of DNA typing results. Due to the multiplicity of forensic sample types and the
55 potential complexity of DNA typing results, it is impractical and infeasible to cover every aspect
56 of DNA interpretation by a preset rule. However, the laboratory should utilize written
57 procedures for interpretation of analytical results with the understanding that specificity in the
58 standard operating procedures will enable greater consistency and accuracy among analysts
59 within a laboratory. It is recommended that standard operating procedures for the interpretation
60 of Y-STR typing results be sufficiently detailed that other forensic DNA analysts can review,

SWGDM Interpretation Guidelines for Y-Chromosome STR Typing

61 understand in full, and assess the laboratory's policies and practices. The laboratory's
62 interpretation guidelines should be based upon validation studies and scientific literature.

63 **Background**

64 Refer to the *SWGDM Interpretation Guidelines for Autosomal STR Typing by Forensic DNA*
65 *Testing Laboratories* for general background information regarding forensic DNA analysis and
66 interpretation.

67 For the purposes of forensic nuclear DNA testing, the typing of autosomal STR loci is generally
68 preferred due to the higher power of discrimination and utility for searching against the National
69 DNA Index System. Y-STR typing is an additional tool that can be used, typically in concert
70 with autosomal typing, in mixed samples with a small proportion of male DNA as compared to
71 total human DNA. Y-STR typing may be used in lieu of autosomal typing for the detection of
72 male DNA in mixtures that contain an overabundance of female DNA. Considering that under
73 certain conditions a minor male contributor in a mixture of male and female DNA may only be
74 detectable by Y-STR typing, laboratories should pursue Y-STR analysis as the most appropriate
75 means of detecting a male contributor(s) in some forensic samples. Due to the transmission of
76 the Y-chromosome within a paternal lineage, Y-STR typing can also aid in the identification of
77 missing persons and familial searches.

78 Y-STR loci exhibit the same general characteristics as autosomal STR loci, namely:

- 79 • Peak height variability, which is inversely proportional to peak heights and manifests as
80 either inconsistencies in mixture proportion, deviations from expected stutter ratios or
81 variation in peak heights between loci.
- 82 • Stutter, to include back stutter and forward stutter. The height of a stutter peak is
83 generally dependent on the parent peak's height, locus and allele length.
- 84 • Allelic peak heights that are the sum of the contributions from each donor to a multiple
85 contributor profile. Allelic peak heights can also be additive with overlapping stutter.
- 86 • Depending on the amplification kit, separating technology, and sample quality/quantity, a
87 general downward trend in peak heights with increasing molecular weight.

SWGDM Interpretation Guidelines for Y-Chromosome STR Typing

- 88 • Allelic drop-out, as expected at low DNA quantity/quality (low either due to initial
89 template amount, PCR inhibition and/or DNA degradation).
- 90 • Allelic drop-in, occurring at a rate which is dependent on the amplification kit and factors
91 that impact sensitivity of detection (e.g., amplification cycle number, detection
92 instrumentation and detection conditions such as the injection voltage and time for
93 capillary electrophoresis).
- 94 • Locus-specific amplification efficiency. The magnitude of differences in amplification
95 efficiency among loci can depend on kit formulation, DNA sample quality and the
96 presence of PCR inhibitors.

97 All Y-STR loci are physically linked on the Y-chromosome. Due to the lack of genetic
98 recombination, the entire Y-chromosome haplotype must be treated as a single locus.
99 Subsequent to a match between two samples using Y-STR testing, a single-source, major, or
100 deduced Y-STR haplotype may be searched against a database of Y-STR haplotypes to obtain
101 the sample frequency of the profile, and, as needed, to calculate profile and/or match
102 probabilities. It is noted that two specimens that exhibit the same Y-STR haplotype may have
103 originated from either a common individual source, from males within the same paternal lineage,
104 or from unrelated individuals. A paternal lineage consists of those male relatives to whom the
105 same Y-chromosome has been transmitted from a common ancestor. Barring mutation, all male
106 relatives within the same paternal lineage have the same Y-STR profile. Attribution of the Y-
107 STR typing results to a single individual, to the exclusion of relatives in the paternal lineage, is
108 generally not possible based on Y-chromosome loci. However, loci with higher mutation rates
109 may enhance the ability to distinguish relatives in the same paternal lineage (Ballantyne et al.
110 2012).

111 **1. Application of Y-STR Typing**

112 1.1 The laboratory should establish guidelines that define the parameters under which
113 samples are subjected to Y-STR typing.

114 1.1.1 Based on STR amplification system and quantification system validations, the
115 laboratory should establish guidelines for when detection of a male contributor to

SWGDM Interpretation Guidelines for Y-Chromosome STR Typing

116 a mixture is not expected with autosomal typing (e.g., based on male to total DNA
117 quantities).

118 **2. Preliminary Evaluation of Data**

119 Refer to the *SWGDM Interpretation Guidelines for Autosomal STR Typing by Forensic*
120 *DNA Testing Laboratories* for general guidance regarding the following topics: analytical
121 threshold, internal standards, allelic ladders, controls and concordance of redundant loci.

122 **3. Allele Designation**

123 Refer to the *SWGDM Interpretation Guidelines for Autosomal STR Typing by Forensic*
124 *DNA Testing Laboratories* for general guidance regarding locus and allele designation.

125 3.1 Alleles should be designated in accordance with recommendations of the DNA
126 Commission of the International Society of Forensic Genetics (Gill et al. 2001 and
127 Gusmão et al. 2006).

128 3.2 The laboratory should establish guidelines based on experimental studies for the
129 identification of null alleles. The guidelines should ensure that a null allele can be
130 distinguished from an undetected allele resulting from low template amounts, DNA
131 degradation or inhibition (i.e., allelic drop-out).

132 **4. Identification of Non-Allelic Peaks**

133 Y-STR typing results generated with the current Y-STR typing kits exhibit the same non-
134 allelic peaks observed in autosomal STR typing results. Refer to the *SWGDM*
135 *Interpretation Guidelines for Autosomal STR Typing by Forensic DNA Testing Laboratories*
136 for general guidance regarding non-allelic peaks and off-scale data.

137 4.1 The laboratory should establish a method based on validation to document the
138 designation of a peak as an artifact or an allele.

SWGDM Interpretation Guidelines for Y-Chromosome STR Typing

139 **5. Application of the Stochastic Thresholds to Allelic Peaks**

140 Refer to the *SWGDM Interpretation Guidelines for Autosomal STR Typing by Forensic*
141 *DNA Testing Laboratories* for general guidance regarding the establishment and usage of the
142 stochastic threshold.

143 5.1 The laboratory should establish a stochastic threshold for known multi-copy Y-STR loci
144 (e.g., DYS385 and DYF387S1) based on empirical data derived within the laboratory and
145 specific to the quantification and amplification systems and the detection instrumentation
146 used.

147 **6. Application of Peak Height Ratios to Multi-copy Y-STR Loci**

148 Refer to the *SWGDM Interpretation Guidelines for Autosomal STR Typing by Forensic*
149 *DNA Testing Laboratories* for general guidance regarding the establishment and usage of
150 peak height ratios.

151 6.1 The laboratory should establish an expected peak height ratio for known multi-copy Y-
152 STR loci (e.g., DYS385 and DYF387S1) based on empirical data derived within the
153 laboratory and specific to the amplification systems and the detection instrumentation
154 used.

155 **7. Number of Contributors to a Y-STR Profile**

156 Refer to the *SWGDM Interpretation Guidelines for Autosomal STR Typing by Forensic*
157 *DNA Testing Laboratories* for general guidance regarding the recognition of mixtures, the
158 minimum number of contributors to a mixture, and the generation of composite profiles.

159 7.1 A laboratory should assess the number of contributors to a Y-STR profile. Y-
160 chromosome profiles typically show one allele per locus except for multi-copy loci (e.g.,
161 DYS385 and DYF387S1). A specimen is generally considered to have originated from
162 more than one male individual if two or more alleles are present at two or more single-
163 copy loci.

SWGDM Interpretation Guidelines for Y-Chromosome STR Typing

164 7.1.1 For a given locus, a laboratory can assess repeat-unit differences among the
165 detected alleles to aid in distinguishing a mixed sample from a single-source
166 sample that exhibits duplication.

167 7.2 The laboratory should establish guidelines based on an assessment of peak heights and
168 peak height ratios for evaluating potential sharing of allelic peaks between major and
169 minor contributors and for determining whether the alleles of the contributors to a mixed
170 DNA typing result are distinguishable.

171 8. Comparison of DNA Typing Results

172 Refer to the *SWGDM Interpretation Guidelines for Autosomal STR Typing by Forensic*
173 *DNA Testing Laboratories* for general guidance regarding the following topics:
174 interpretation of evidentiary profiles relative to that of known profiles, partial profiles,
175 possible conclusions, full accounting of mixed results, documentation of assumptions, and
176 results for which no comparisons will be made.

177 8.1 The laboratory should establish guidelines, based on internal validations, for determining
178 whether a Y-STR typing result is suitable for comparisons.

179 8.2 Single-source Y-STR haplotypes, including partial haplotypes, may be used for
180 comparison purposes, inclusionary and exclusionary. The laboratory should establish the
181 minimum number of loci from an evidentiary profile required to perform a comparison to
182 a reference profile.

183 8.3 Mixtures of DNA from more than one male individual may also be used for comparison
184 purposes when the contributors can be distinguished based on means such as peak height
185 ratio comparisons. These deduced haplotypes are then used for comparison as in 8.2.
186 Such haplotypes include (a) those of major, and potentially minor, contributor(s) to a
187 distinguishable mixture, and (b) for an indistinguishable mixture, those foreign alleles
188 derived from separation of a conditional known sample type (e.g., from the consensual
189 partner).

SWGDM Interpretation Guidelines for Y-Chromosome STR Typing

190 8.4 The laboratory should establish guidelines for identifying mixtures for which no major or
191 minor contributor can be discerned. Interpretation and comparison of indistinguishable
192 Y-STR mixtures shall be supported by internal validations.

193 9. Statistical Analysis of Y-STR Typing Results

194 Refer to the *SWGDM Interpretation Guidelines for Autosomal STR Typing by Forensic*
195 *DNA Testing Laboratories* for general guidance regarding the following topics: when to
196 perform statistical analysis, data appropriate for use in statistical analysis, and reporting of
197 statistical analysis.

198 9.1 The Y-Chromosome Haplotype Reference Database (YHRD, Willuweit and Roewer
199 2007) available at <https://yhrd.org/> contains a U.S. Y-STR population database which
200 should be used for estimation of profile (i.e., haplotype) probabilities and match
201 probabilities. As this database is regularly updated with population data from new
202 population studies (for example, Carrecedo et al. 2010), it is advised to state the YHRD
203 release for traceability.

204 9.2 Statistical Analysis of Single-Source and Deduced Single-Source Y-STR Haplotypes

205 9.2.1 The laboratory should establish guidelines for the number of Y-STR loci used for
206 searches of population databases. Due to the challenge of small database sizes for
207 the larger multiplex systems, it is acceptable to perform additional searches of the
208 population database using reduced locus sets in an attempt to obtain the most
209 informative result for that combination of evidence and population database
210 profiles.

211 9.2.1.1 Regardless of the number or selection of loci searched, the most
212 informative search is generally the one which gave the lowest proportion
213 of matching haplotypes per number of profiles compared.

214 9.2.1.2 When performing reduced locus-count searches, any “matches” that
215 would have been non-matches had more of the evidence profile been

SWGDM Interpretation Guidelines for Y-Chromosome STR Typing

216 searched must be excluded. For example, a “match” between the
217 evidence and a population database sample at 8 loci in YHRD’s minimal
218 haplotype would not be included as a match for statistical purposes if the
219 profiles differed at any additional loci for which they both had
220 information.

221 9.2.2 The laboratory should determine which of the following methods will be used to
222 determine the haplotype sample frequencies.

223 9.2.2.1 A Y haplotype sample frequency can be determined using the observed
224 counting method. The Y haplotype sample frequency (p) is calculated
225 using $p = x/n$ formula, where x is equal to the number of times the
226 haplotype is observed in the database containing n number of haplotypes
227 in the database.

228 9.2.2.2 A Y haplotype sample frequency can be determined using the
229 augmented counting method. This Y haplotype sample frequency (p) is
230 calculated using the $p = (x+1)/(n+1)$ formula, where x is equal to the
231 number of times the haplotype is observed in a database and n is equal to
232 the number of haplotypes in the database (Gjertson, et al. 2007).

233 9.2.3 A Y-STR haplotype upper bound profile probability estimate can be calculated
234 from the observed or augmented haplotype frequencies by including a confidence
235 interval (generally 95% or greater) to capture the effect of database size (Clopper
236 and Pearson 1934). The laboratory should establish if an upper confidence limit
237 for the haplotype probability or a confidence interval for the haplotype probability
238 will be calculated and reported.

239 9.2.4 The laboratory should determine if match probabilities will be used and the
240 method to calculate them. There is no consensus from statistical subject matter
241 experts as to the best or preferred method for calculating match probabilities. See
242 Brenner (2010), Budowle (2009), and Weir and Goudet (2017) and the

SWGDM Interpretation Guidelines for Y-Chromosome STR Typing

243 *Supplemental Information for the SWGDAM Interpretation Guidelines for Y-*
244 *Chromosome STR Typing by Forensic DNA Laboratories* document.

245 9.2.5 The laboratory should determine if likelihood ratios will be used to provide
246 quantitative assessments of the value of the matches using relevant populations.
247 An approach is described in Evett and Weir (1998) and is recommended by the
248 DNA Commission of the International Society of Forensic Genetics (Roewer, et
249 al. 2020).

250 9.3 Statistical Analysis of Indistinguishable Y-STR Mixtures

251 9.3.1 A laboratory choosing to report inclusionary Y-STR typing results from
252 indistinguishable mixtures must perform statistical analysis in support of any
253 inclusion determined to be relevant in the context of the case.

254 10. Combining Lineage Markers and Autosomal Results

255 10.1 If there is reasonable expectation of genetic independence, match probabilities from any
256 combination of mtDNA, Y-STR and/or autosomal STRs may be combined. Such an
257 expectation could arise from large scale independence testing or strong population
258 genetic models (Walsh and Hammer 2008, Buckleton and Myers 2014).

DRAFT

SWGDAM Interpretation Guidelines for Y-Chromosome STR Typing

318 **Glossary**

319 Refer to the *SWGDAM Interpretation Guidelines for Autosomal STR Typing by Forensic*
320 *DNA Testing Laboratories* for definitions of terms. Additional terms used in this document
321 are defined below.

322

323 **Back stutter:** A PCR artifactual peak typically one repeat unit shorter than the parent allele.
324 Two repeat units or partial repeat units may also be observed.

325

326 **Deduced Single-Source Y-STR Haplotype:** A Y-haplotype from one contributor
327 determined from a mixture, usually by inference of an unknown contributor's DNA profile
328 after taking into consideration the contribution of a known male contributor's alleles, if
329 appropriate, or quantitative peak height information.

330

331 **Drop-in:** The random appearance of non-reproducible allelic peaks in a profile thought to
332 arise from fragments of cells introduced into the extract and not from the principal donors.

333

334 **Drop-out:** The event where an allele in the sample does not produce a peak above the
335 analytical threshold.

336

337 **Forward stutter:** A PCR artifactual peak typically one repeat unit longer than the parent
338 allele. Two repeat units or partial repeat units may also be observed.

339

340 **Indistinguishable mixture:** a DNA mixture in which relative peak height ratios are
341 insufficient to attribute alleles to individual contributor(s).

342

343 **Null (silent) allele:** An allele which cannot be detected due to lack of amplification product,
344 often caused by a mutation in the primer binding site, or deletion of the primer binding site or
345 locus.

346

SWGDM Interpretation Guidelines for Y-Chromosome STR Typing

347

Revision History

Document Version	Revision History
January 2009	Original. Published in Forensic Science Communications in January 2009, Vol. 11, No. 1.
January 2014	The document was revised to reflect the current state of forensic Y-STR typing. Additional information was added regarding multi-copy and duplicated loci as well as null alleles. The statistical treatment of Y-STR haplotypes was expanded to include an appendix of theta values, references to the US Y-STR database and the calculation of match probabilities. The use of Clopper-Pearson as an upper confidence interval was added.
July 2021	This document contains several revisions to the 2014 guidelines and is intended to reflect the current state of forensic Y-STR typing. The statistical treatment of Y-STR haplotypes includes the use of YHRD, augmented counting method, and multiple match probability options. Removal of U.S. Y-STR database use and appendix of theta values.

348
